2. Estructuras

2.1. RMQ (static)

Dado un arreglo y una operacion asociativa *idempotente*, get(i, j) opera sobre el rango [i, j). Restriccion: $LVL \geq \text{ceil}(\log n)$; Usar [] para llenar arreglo y luego build().

```

1 struct RMQ{
2     #define LVL 10
3     tipo vec[LVL][1<<(LVL+1)];
4     tipo &operator[](int p){return vec[0][p];}
5     tipo get(int i, int j) { //intervalo [i,j)
6         int p = 31-__builtin_clz(j-i);
7         return min(vec[p][i], vec[p][j-(1<<p)]);
8     }
9     void build(int n) { //O(nlogn)
10        int mp = 31-__builtin_clz(n);
11        for(p, mp) for(x, n-(1<<p))

3  Sirve para encontrar el i-esimo numero de un conjunto de numeros que
   vamos insertando en el arbol.
4  Sirve solo si nuestros numeros son del 0 al n-1 (pero podemos mapearlos
   antes de usarlos)
5  La idea es esta:
6  Funcionamiento:
7  - En el fondo sigue siendo un Segment-Tree (hacemos que 'n' sea 2^x)
8  - Cada nodo guarda cuantos numeros hay en el intervalo (entonces en
   tree[1] dice cuantos numeros tenemos en total)
9  - Se sigue representando los hijos del nodo 'i' con '2 * i' (izq) y '2
   * i + 1' (der);
10 Query:
11 - si kth es mas grande que todos los que tenemos(tree[1]) o es
   negativo entonces -1
12 - siempre nos mantenemos en el nodo de la izquierda y si es necario
   avanzamos al de la derecha
13     'i <= 1'
14 - si kth es mas grande que el nodo de la izquierda(el actual) quiere
   decir que podemos quitarle todos esos

```

```

15     numeros a nuestra busqueda 'kth - tree[i]' y buscar el nuevo kth en
   el arbol de la derecha
16     if (kth > tree [i]) kth -= tree [i++];
17     - Ojo en el 'i++' ahi es donde avanzamos al nodo de la derecha
18     - luego hace su formula rara que aun no entendi xD:
19     'i - leaf + (kth > tree [i])';

5 Brief explanation when use Mo:
6 Explain where and when we can use above algorithm
7
8 As mentioned, this algorithm is offline, that means we cannot use it
    when we are forced to stick to given order of queries.
9 That also means we cannot use this when there are update operations.
    Not just that, there is one important possible limitation:
10 We should be able to write the functions add and remove. There will be
    many cases where add is trivial but remove is not.
11 One such example is where we want maximum in a range. As we add elements
    , we can keep track of maximum. But when we remove elements

```

```

12 it is not trivial. Anyways in that case we can use a set to add elements
    , remove elements and report minimum.
13 In that case the add and delete operations are  $O(\log N)$  (Resulting in  $O(N * \sqrt{N} * \log N)$  algorithm).
14
15 Suggestion first use the add operation, then the erase operation

22         reconstruct(pos + 1, capacity - weight[pos]) + profit[pos];
23     }
24 }

```

After executing reconstruct, it will print all those objects that give you the optimal solution. As you can see, at most no_of_objects calls will be made in the reconstruct function.

Similarly, you can reconstruct the solution of any DP greedily.
